 - AUTOREGRESSIVE MODELS
- DATA STREAM MINING
 - INCREMENTAL ALGORITHMS

QUESTIONS?

AGENDA

```
I. BIG DATA
II. HADOOP (MAPREDUCE + HDFS)
III. THE HADOOP ECOSYSTEM
IV. SPARK
HANDS-ON: PYSPARK
V. AWS
```

LEARNING GOALS

- What is big data?
 - What challenges does it pose?
- What is Hadoop?
 - What is MapReduce?
 - What is HDFS?
- What are the elements of the Hadoop stack and what do they do?
- What is the goal of Spark?
- What services does AWS provide?

INTRO TO DATA SCIENCE

I. BIG DATA

- Q: **Big Data** is a hot topic these days, what does it actually refer to? A:
- **Volume**: more data than can fit in memory on 1 machine
- **Velocity**: data coming in faster than we can process (think Twitter)
- Variety: Data across all different types
- **Veracity**: Uncertainty of data

The FOUR V's of Big Data

From haffic patterns and music downloads to well hashiny and medical records, data is recorded, strend, and analyzed to make the fact-holings and sensors that the world relies on every day flut what exactly is big data, and how can these makes the property of the control o

As a leader in the sector, ISM data sciential break big data into four dimensions. **Value Velocity**, **Watery** and **Breakly**

Depending on the industry and organization, by data encompasses information from multiple information death and applications and adental sources such as framacions, social media, enterprise centent, sensors and media, enterprise centent, sensors and media devices. Companies can be orage data to adapt their products and services to bother most cystomer needs, upd limites operations and

0y 2015 4.4 MILLION IT JOBS

ell be created globally to support big data, eth. 1.9 million in the United States.

don't trust the information they use to make decisions

in one survey were unsure of how much of their data was inaccurate Pror data quality cods the US sconomy around \$3.1 TRILLION A YEAR

Q: **Big Data** is a hot topic these days, what does it actually refer to?

A:

We're talking about more data than can fit on a single computer.

We have exponentially growing data AND exponentially growing computing power.

- The Large Hadron Collider produces about 30 petabytes of data each year
- A petabyte is 10¹⁵ bytes, or a million gigabytes
- Their data center contains over 10,000 servers with around 100,000 processor cores
- They can process around 1 petabyte of data per day!

- Q: How do we handle all of this data?
- A: One approach would be to build a giant supercomputer.

But this has some obvious drawbacks:

- expensive
- difficult to maintain
- scalability is bounded

Instead of one huge machine, what if we got a bunch of regular (commodity) machines?

This has obvious benefits!

- cheaper
- easier to maintain
- scalability is unbounded (just add more nodes to the cluster)

This idea leads us to **Hadoop**

INTRO TO DATA SCIENCE

II. HADOOP

Q: What is Hadoop?

A: A platform/framework for distributed computing.

Arose out of several papers from Google in the early 2000s.

Allows scaling big data analysis outwards over clusters of computers.

Handles fault tolerance, scheduling, monitoring

- Q: What is Hadoop?
- A: At its core, it consists of 2 components:
- Hadoop Distributed Filesystem (HDFS):
 - Filesystem optimized for dealing with big data on clusters of computers
- MapReduce:
 - Functional programming paradigm for simplifying large scale highly parallelizable computations

INTRO TO DATA SCIENCE

HDFS

- Q: What is HDFS?
- A: Hadoop Distributed Filesystem
- Based on Google Filesystem (GFS) from early 2000s paper.
- Distributed filesystem across cluster of machines
- Highly fault tolerant
- Designed to be deployed on commodity hardware
- Can store and work with massive files across many computers
- A cluster is a group of machines (nodes) working together

NameNode: Runs on a master node that tracks and directs the storage of the cluster

DataNode: Runs on slave nodes that make up the majority of the machines in the cluster. Handles storage of data files in blocks (much larger than usual file block size) which are replicated several times (3 by default) on data nodes across the cluster.

Client Nodes: Not actually storing data, but may run other Hadoop services and processes.

INTRO TO DATA SCIENCE

MAPREDUCE

Q: What is MapReduce?

A: Functional programming paradigm designed to simplify appropriately parallelizable large-scale computations.

Originated from another early 2000s Google paper.

Great for certain "embarrassingly parallel problems", not so great for a lot of other types of problems.

- Let's consider the word frequency problem...
- How would you count the words in a list containing, 10³, 10⁶, 10⁹ words?

```
def count_words(words_list):
    counts = {}
    for word in words_list:
        counts[word] += 1
```

- What's the downside to this approach?
 - We have to hold this whole dictionary in memory.
- How can we solve this if the data is too big for that?
 - Use a cluster of many machines, send each a chunk of the data, then aggregate the results
- What issues might we still face?
 - Network bandwidth trying to move all that data around
- So how can we solve this last hurdle?
 - Move the code to the data rather than moving the data!

MAPREDUCE IN HADOOP

- With HDFS, we have our data effectively distributed across the cluster
- As best as possible, when we run a map reduce job, Hadoop tries to ensure that each individual worker node only operates on data that is local to it

ASIDE: DIVIDE AND CONQUER ALGORITHMS

Divide and conquer is a fundamental algorithmic technique for solving a given task, whose steps include:

- 1) split task into subtasks
- 2) solve these subtasks independently
- 3) recombine the subtask results into a final result

Map-reduce leverages the divide and conquer approach by splitting a large dataset into several smaller datasets and performing a computation on each of these in parallel.

ASIDE: DIVIDE AND CONQUER ALGORITHMS

The defining characteristic of a problem that is suitable for the divide and conquer approach is that it can be broken down into independent subtasks.

Tasks that can be parallelized in this way include:

- count, sum, average
- grep, sort, inverted index
- graph traversals, some ML algorithms

NOTE

Parallelizing a ML algorithm can be a non-trivial exercise!

As we've discussed, the map-reduce approach involves splitting a problem into subtasks and processing these subtasks in parallel.

This takes place in (approximately) two phases:

- 1) the mapper phase
- 1.5) shuffle/sort
- 2) the reducer phase

To implement MapReduce, you have to (at a minimum) write 2 functions:

- 1) the mapper: filter and transform data
 - (key, value) —> (key, value)
- 2) the reducer: outputs a new (key, value) by aggregating pairs with matching keys via some user-defined aggregation function
 - (key, List<values>) —> (key, value)

Hadoop will handle everything else for you if you want.

Map-reduce processes data in terms of key-value pairs:

```
input <k1, v1> mapper <k1, v1> \rightarrow <k2, v2> <k2, v2> <k2, [all k2 values]> reducer <k2, [all k2 values]> \rightarrow <k3, v3>
```

MAP-REDUCE

As our earlier diagram suggests, there are additional intermediate steps in a map-reduce workflow.

mappers — filter & transform data

combiners — perform reducer operations on the mapper node (optional step, to reduce network traffic and disk I/O).

partitioners — shuffle/sort/redirect mapper output

reducers — aggregate results

Using the following input, we can implement the "Hello World" of map-reduce: a word count.

```
where in where in the where in the world where in the world is where in the world is carmen where in the world is carmen sandiego
```

The first processing primitive is the mapper, which filters & transforms the input data, and emits transformed key-value pairs.

```
mapper(k1, v1):
// k1 = line number
// v1 = line contents (eg, space-delimited string)

words = tokenize(v1) // split string into words
for word in words:
    emit (word, 1)
```

The mapper emits key-value pairs for each word encountered in the input data.

```
where 1 in 1 where 1 in 1 the 1
```

The partitioner is internal to the map-reduce framework, so we don't have to write this ourselves. It shuffles & sorts the mapper output, and redirects all intermediate results for a given key to a single reducer.

```
where
    [1, 1, 1, 1, 1, 1, 1]
in
    [1, 1, 1, 1, 1, 1]
the
    [1, 1, 1, 1, 1]
world
is
    [1, 1, 1, 1]
carmen
    [1, 1]
sandiego
[1, 1]
```

Finally, the reducer receives all values for a given key and aggregates (in this case, sums) the results.

```
reducer(k2, k2_vals):
// k2 = word
// k2_vals = word counts
emit k2, sum(k2_vals)
```

Reducer output is aggregated & sorted by key.

```
carmen 2
is 3
in 6
the 5
sandiego 1
where 7
world 4
```

WORD COUNT IN MAP-REDUCE

The map-reduce framework handles a lot of messy details for you:

- parallelization & distribution (eg, input splitting)
- partitioning (shuffle/sort/redirect)
- fault-tolerance (fact: tasks/nodes will fail!)
- I/O scheduling
- status and monitoring

This (along with the functional semantics) allows you to focus on solving the problem instead of accounting & housekeeping details.

III. THE HADOOP STACK

HADOOP ECOSYSTEM

It's possible to overlay the map-reduce framework with an additional declarative syntax.

This makes operations like select & join easier to implement and less error prone.

Popular examples include Pig and Hive.

Apache Hive

- SQL language to query data on HDFS
- Queries are translated behind the scenes into map-reduce jobs
- Data is stored on HDFS, but a metadata database contains the table schemas

Cloudera Impala

- **ANOTHER** SQL language to query data on HDFS
- Similar interface to Hive

BUT:

- Impala contains its own scheduling engine, queries are not translated map-reduce jobs
 - Leads to faster queries, but no fault tolerance

Apache Pig

- Scripting language to operate on data on HDFS
- Queries are translated behind the scenes into map-reduce jobs
- Allows for similar declarative functionality to hive, but often in a simpler and more intuitive scripting format

Why Pig?

Because I bet you can read the following script.

A Real Pig Script

```
top_5.pig
users = load 'users.csv' as (username: chararray, age: int); -
users 1825 = filter users by age >= 18 and age <= 25;
pages = load 'pages.csv' as (username: chararray, url: chararray); -
joined = join users_1825 by username, pages by username; -
grouped = group joined by url;-
summed = foreach grouped generate group as url, COUNT(joined) AS views;
sorted = order summed by views desc;
top 5 = limit sorted 5;
     top_5 into 'top_5_sites.csv';
```

Now, just for fun... the same calculation in vanilla Hadoop MapReduce.

No, seriously.

```
Tal substitution (Talenting of Sancting of
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       It has the come graduat and extinct the values

HADOOP ECOSYSTEM

Apache Sqoop

- Utility for moving data between relational databases and Distributed file systems (import/export)
- Automatically generates efficient map-reduce jobs for your bulk move

Apache Oozie

- Job-chaining utility
- Allows you to plan directed graphs of sequential jobs with conditional path execution

Apache Zookeeper

- Central coordination service used by many of the services in the Hadoop ecosystem to stay in lockstep

HADOOP PROVIDERS

CLOUDERA CDH 51

INTRO TO DATA SCIENCE

IV. SPARK

- With distributed systems like Hadoop, we have tools for collecting, storing, and processing information at scale.
- Having access to all this data is one thing, being able to do something useful with it is something entirely different.
- Doing something useful means placing a schema over the data and using, say, SQL, to answer questions like: "of the millions of users who made it to the 3rd page of our registration process, how many were over 25?"

- In general, "doing something useful" means more than just SQL
- We want richer functionality in areas like ML and statistics

- The sorts of things we have been doing with data in our IPython notebooks are the sorts of things we would like to do to leverage the huge datasets residing on our HDFS, which is spread over our cluster
- One idea might be to push our ML framework onto the machines, having rewritten them to work in a distributed setting.
- The problem is that many algorithms have wide data dependencies, and network transfer rates are considerably slower than in-memory access.

- Thus there is a need for a programming paradigm that is by its very nature highly parallel
- Genomics has had HPC, or high-performance computing for decades
- The problems with HPC are in its difficulty in use
- Hadoop gives the mainstream user many of the features of HPC at a far cheaper cost...
- So how do we do data science on massive data?

- 1. Most of our work is in preprocessing the data
 - You will have to preprocess data that you can't inspect directly
- Preprocessing becomes even more computationally dependent
- 2. Iteration is fundamental to data science
 - There is a requirement for multiple passes over the data
 - Experimentation intrinsic (feature/model selection, optimization, etc)
- 3. The task isn't over when a good model has been built
 - Models must be productionized and maintained
 - Ideally, we need a REPL, (Read-Evaluate-Print-Loop) environment

- Spark aims to provide the solution to this
- Q: What is Spark?

A: An open source framework that combines an engine to distribute programs across clusters of machines with an elegant model for writing programs on top of it.

Arguably the first open source software that makes distributed programming truly accessible to the data science workflow!

SPARK CORE

- Spark Core: contains the basic functionality of Spark
 - APIs that define Resilient Distributed Datasets (RDDs) and operations and actions that can be performed on them
 - The rest of Spark's libraries are built on top of the RDD and Spark

 Core

- Spark SQL:
 - APIs for interacting with data in Spark via the Apache Hive variant of SQL HiveQL (Hive Query Language)
 - Every DB table is represented as an RDD and Spark SQL queries are translated to Spark Operations
 - Can function as drop-in replacement for Hive

SPARK STREAMING

- Spark Streaming:
 - Enables the processing and manipulation of live data streams in real time
 - Many streaming data libraries (e.g. Apache Storm) exist for handling streaming data in real-time
 - Spark Streaming enables programs to leverage this data similar to how you would interact with a normal RDD as data is flowing in

SPARK MLLIB

- Spark MLLib:
 - A library of common ML algorithms implemented as Spark operations on RDDs
 - Contains scalable algorithms like classifications, regressions, etc
 - Mahout, the former choice for this task, will move to Spark for future things

- Spark maintains MapReduce's linear scalability and fault tolerance, but extends it in 3 ways:
 - Does not rely on a rigid map-then-reduce paradigm. Its engine can implement a Directed Acyclic Graph (DAG) of operators.
 - It complements this with a rich set of transformations that allow users to express computations more naturally (developer focused)
 - It has in-memory processing; it has RDD abstraction, meaning future steps requiring the same data do NOT need to be recomputed or reloaded from disk

SPARK HIGHLIGHTS

- Highly suited for iterative algorithms requiring multiple data passes
- Aim is to bring data science into a single programming environment
- It aims to be the Python of big data!
- Native language is Scala, but has Python API PySpark
- With Scala, you can perform the entire data science pipeline. You don't have to query to get the data and then do your analysis in R or Python, it's all unified and the details invisible to the user.

SPARK HIGHLIGHTS

- Read/write data in all formats supported by MR (Avro, Parquet, CSV)
- Read/write from/to NoSQL DBs like HBase or Cassandra
- Spark streaming can ingest data continuously from streaming sources like Flume
- SparkSQL can use the underlying Hive engine for data interaction
- Can run inside YARN, Hadoop's scheduler and resource manager

SPARK WORDS OF CAUTION

- STILL A WORK IN PROGRESS
- Hasn't surpassed MR as the workhorse of batch processing
- SQL, MLLib, Streaming, GraphX all still under development
- Nowhere near the full-featured ML of R, Python, etc.
- SQL is rich, but still lags behind Hive

SPARK PROGRAMMING

- Writing a Spark program usually consists of:
 - Defining a set of transformations on input datasets
 - Invoking actions that output the transformed datasets into persistent storage or return results to the driver's local memory
 - Running local computations that operate on the results computed in a distributed fashion. These can help you decide what actions and transformations to undertake next

HANDS-ON: PYSPARK

V. AMAZON WEB SERVICES

Amazon provides a suite of services to allow you to easily manage all of your servers (hardware, software, OS) completely in the Amazon cloud.

This is called Amazon Web Services (AWS)

Compute

- ec2: resizable compute capacity in the cloud
- lambda: run code immediately in response to events like website clicks, service requests

Storage

- s3: secure, durable, scalable object storage
- Storage Gateway: connect onpremises hardware with cloud
- Glacier: long term archival storage
- Cloudfront: deliver content to users

amazor

Databases

- RDS: run relational DBs
- DynamoDB: NoSQL DB in the cloud
- ElastiCache: In-memory keyvalue cache
- Redshift: Data Warehousing in the cloud

Networking

- VPC: provision segment of cloud for private network
- Direct Connect: private connection directly to AWS cloud
- Route 53: DNS Server

Admin/Security

- Directory Service: use Microsoft ActiveDirectory
- IAM: Control access to resources/services
- Trusted Advisor: advise on best practices
- CloudTrail: log AWS API calls
- Config: Configuration management
- CloudWatch: monitor resources

Deployment/Management

- Elastic Beanstalk: Web application deployment
- OpsWorks: Custom application deployment
- CloudFormation: Provision AWS resources
- CodeDeploy: Automated code deployment

Analytics

- EMR: Managed Hadoop, Spark framework
- Kinesis: Data stream processing
- DataPipeline: Data processing/transfer at regular intervals
